(57) **ABSTRACT**

A hand truck for carrying and lifting a load comprising spaced vertical columns each having a channel. Rollers are captured in each of said channels that are capable of vertical movement along its respective channel. A first toe plate is affixed to said columns and adapted to extend horizontally during use. A second toe plate is attached to the rollers and adapted to move vertically along said columns between upper and lower positions. The first and second toe plates are in nesting relationship when the second toe plate is in its lower position.

HAND TRUCK**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application claims the benefit of U.S. Provisional Patent Application No. 61/507,389, entitled "Hand Truck" filed Jul. 13, 2011, the disclosure of which incorporated herein by reference in its entirety.

TECHNICAL FIELD

This application relates to a hand truck and more particularly to a hand truck for transporting and lifting a load.

BACKGROUND

The handling of material in tight spaces required, in many instances, the use of simple hand carts that could not lift, or heavier lifting systems that were expensive and difficult to maneuver. As a result, there is a need for a light and efficient hand truck that can provide for both the moving and lifting of materials that is light in weight, cost efficient and ergonomic.

SUMMARY

According to one aspect of the disclosure there is provided a hand truck for carrying and lifting a load comprising spaced vertical columns each having a channel. Rollers are captured in each of said channels that are capable of vertical movement along its respective channel. A first toe plate is affixed to said columns and adapted to extend horizontally during use. A second toe plate is attached to the rollers and adapted to move vertically along the columns between upper and lower positions; the first and second toe plates are in nesting relationship when the second toe plate is in its lower position.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

FIG. 1 is a perspective view of the hand truck with the inner toe plate in a raised position;

FIG. 2 is a perspective view showing the hand truck in a collapsed position;

FIG. 3 is a sectional view showing the relationship of the three columns, panels and trolley member;

FIG. 4 is a plan view and side view of the center toe plate;

FIG. 5 is a plan view and side view of the outer toe plate;

FIG. 6 is a side view showing the toe plates in the collapsed position;

FIG. 7 is a horizontal sectional view through one of the outside masts or column;

FIG. 8 is an isometric exploded view of the split nut assembly;

FIG. 9 is an isometric view of the split nut assembly showing it in assembled condition.

FIG. 10 is a view similar to FIG. 8, but showing an alternative configuration of the channels and rollers;

FIG. 11 is a perspective view of a second embodiment of a hand truck in a collapsed position;

FIG. 12 is a perspective view of the embodiment of FIG. 11 showing the toe plates in the extended position and the handles raised.

FIG. 13 is an isometric exploded view showing how various components of the second embodiment fit together;

FIG. 14 and FIG. 14A are an isometric view and top view respectively of a lifting bracket;

2

FIG. 15 is an isometric view of the bottom toe plate of the second embodiment;

FIG. 16 is an isometric view of the upper toe plate of the second embodiment;

FIG. 17 is an isometric view of the toe plates attached to the hand truck and showing the upper toe plate in a raised position.

FIG. 17A is an isometric view of the toe plates attached to the hand truck and showing the upper toe plate in its lower position nesting with the lower toe plate.

FIG. 18 is an isometric schematic view showing the electrical drive arrangement; and

FIG. 19 is a partial isometric view showing one of the wheels of the hand truck.

DETAILED DESCRIPTION OF THE INVENTION

In general, the hand truck comprises three spaced vertical extending masts or columns **2**, **4**, **6** aligned in a row. The two outside columns **2** and **6** are mirror images of each other while the center column **4** is of a different structure. The panels **8** and **10** run the entire length of the columns **2**, **4** and **6**. Two panels **8** and **10** are provided, one on each side of the center column **4** connected between the center column **4** and a respective outside column **2** or **6**. A top and bottom cross bracket **12** and **14** interconnects the three columns **2**, **4** and **6**. Spaced wheels **16** are connected by suitable means to the bottom bracket **14** at the rear of the hand truck as shown.

The hand truck includes two toe plates, one nesting inside the other, providing an inner toe plate **18** and an outer toe plate **20**. When the plates are in the nested position with the inner toe plate **18** in its lower position, the upper surfaces of the two toe plates **18** and **20** are coplanar. The outside toe plate **20** is stationary during use to provide stability while lifting. The inner toe plate **18** provides a lifting platform and is moveable upwardly and downwardly in a vertical direction along the columns **2** and **6**. Both the inside **18** and outside **20** toe plates are pivotal upwardly into a collapsed position as shown in FIG. 2 wherein they extend vertically parallel to the elongated columns **2**, **4** and **6**.

A handle **22** is provided having two elongated vertical posts **24** that extend into the outer columns **2** and **6**. The handle **22** is vertically moveable between a raised position as shown in FIG. 1 and a collapsed position as shown in FIG. 2.

More specifically, the outside columns **2** and **6** as shown in FIG. 7 are elongated extrusions and are mirror images of each other. Each column **2** and **6** includes a general circular channel **26** at the rear for receiving the posts **24** of the handle **22**. A slot **28**, opening to the inside, is provided at the front portion of the columns **2** and **6** to receive the panels **8** or **10**. An open channel portion **30** positioned between the circular channel **26** and slot **28** is provided that opens to the inside to capture the rollers **32** of a trolley member **34** as shown in FIG. 3. This portion **30** has opposed convex walls **31** that mate with the concave surfaces **133** of the roller **32**. A channel **35** opening to the outside allows for rotation of the toe plates for storage.

An alternative arrangement for the channel portion **30** of the columns **2** and **6** containing the rollers **32** is shown in FIG. 10. In this case, each roller **32** has a concave surface **133** that has a greater diameter at its inside edge **134** than at its outside edge **136**. The opposed walls **131** of the channel portion **30** of each of the columns **2** and **6** are convex having a mating contour to mate with the outside surface of the roller **32**.

The top and bottom cross brackets **12** and **14** are drawn together and held against the ends of the columns **2** and **6** by tension rods **15** extending through bore **27** in each of the

3

outside columns **2** and **6**. The rods **15** have threaded ends that extend through the top and bottom cross brackets **12** and **14** and are fastened in tension with suitable nuts.

As shown in FIG. 3, the center column **4** includes a center circular channel **36** having a forward facing slot **38** running the length thereof. Two projections **40** extend rearward toward the outside as shown and are provided with slots **42** to receive the edge portion of a respective panel **8** or **10**. As shown in FIG. 3, each panel **8** and **10** extends between the slot **42** in the center column **4** and the slot **28** in a respective outer column **2** or **6**.

A screw member **44**, driven by a suitable motor **145** is positioned for rotation in the center circular channel **26** in the center column **4**. A connector, shown in FIGS. 8 and 9, includes a split nut **46** positioned in the center circular channel **36** around the screw **44**. Each half of the nut has a forward flange portion **47** that extends through the slot **38** and which is connected to the trolley member **34**.

Each half of the split nut **46** has a reduced diameter upper and lower portion **48**. A nut ring **50** is positioned around the reduced diameter portions **48** to hold the two halves of the split nut **46** together. A bolt **52** and nut **54** secure the two flange portions together as shown. The head of the bolt **52** and nut **54** are countersunk. The nut **46** has internal threads to mate with the threads on the screw shaft **44** so that rotation of the shaft **44** causes the nut **46** to ride up and down on the shaft **44**.

The trolley member **34** as shown in FIG. 3 extends between the two outside columns **2** and **6** and includes a front portion **56** with a side flange **58** extending rearward from each end of the front portion **56** as shown in FIG. 3. Each flange **56**, has an upper roller **60** and lower roller **62** (as designated in FIG. 6) attached thereto by a shaft **64**. The rollers **60** and **62** are contained within the inside open channel portion **30** of a respective one of the outside columns **2** and **6**.

The inner toe plate **18** includes a flat lifting platform **66** with spaced upstanding flanges **68** extending to the rear on either side thereof. The flanges **68** have a bore **70** there through adjacent their upper edge through which the shaft **64** of the upper rollers **60** of the trolley member **34** extend. With this arrangement, the inner toe plate **18** is attached to the trolley member **34** while being able to pivot upwardly around the roller shaft **64** into its collapsed position. Downward pivotal movement is limited by a notch **72** on the bottom of the flange **68** that engages the shaft **64** of the bottom rollers **62** of the trolley member **34** when the inner toe plate **18** is in its horizontal position.

The outer toe plate **70** as shown in FIG. 6 is generally U-Shaped with a forward portion **74** and two legs **76** extending rearward from the sides of the forward portion **74**. The forward portion **74** has a planar upper surface that is coplanar with the upper surface of the inner toe plate **18** when the inner toe plate **18** is in its bottom position. The outer toe plate **70** surrounds the inner toe plate **18** on three sides when the inner toe plate **18** is in its bottom position so that the inner toe plate **18** is nested within the outer toe plate **70**. The forward edge **78** of the outer toe plate **70** is provided with an L-shaped cutout **80** as shown in FIGS. 1 and 2. This shape enables the outer toe plate **20** to grab the outside corner of a box to make it easier to scoop under the box.

Each leg **76** of the outer toe plate **20** has an upstanding flange **82** at its inner end which is pivotally attached to a respective outer column **2** or **6**. A suitable latch mechanism (not shown) latches the outer toe plate **20** in its horizontal position whereby the outer toe plate **20** serves to hold the columns in their upright vertical position and provides stability to the hand truck in the vertical position. Release of the

4

latch mechanism allows the bottom toe plate to be folded upwardly into the vertical position as shown in FIG. 2 for storage.

As shown in FIG. 1, the handle **22** includes a cross member **84** having legs **86** extending forwardly from each end thereof. Each leg **86** is connected to one of the posts **24** that extending vertically downwardly therefrom and which is received in the circular channel **26** in a respective outer column **2** and **6**. With this arrangement the handle **24** can be moved upward and downward between an upper position as shown in FIG. 1 and a collapsed position as shown in FIG. 2. A suitable locking mechanism (not shown) may be provided to hold the handle **24** in its various positions.

The drive train includes the screw member **44** contained in the center column **4**. A cordless DC rechargeable 14.4 volt battery pack and a suitable motor **145** may be provided and can be mounted on the bottom cross bracket **14**. A suitable drive connection, including a gear box may be provided between the motor and screw member **44** to enable the motor to rotate the screw member **44** and move the two-piece nut **46** up and down along the screw member **44**. Various controls may also be included including an up/down button which, when depressed, will cause the screw to turn and raise or lower the inner toe plate **18** with the load. Upper and lower limit switches may be provided to shut off the motor when the extreme upper and lower positions of the inner toe plate **18** are contacted.

A suitable brake mechanism, such as shown in U.S. Pat. No. 7,712,682, issued May 11, 2010 to Burton et al., entitled Lifting Device and Method may be provided. The disclosure of this U.S. Pat. No. 7,712,682 is incorporated herein by reference in its entirety.

Preferably, the columns **2**, **4** and **6** are each a unitary one-piece structure. The columns **2**, **4** and **6** may be extrusions fabricated from aluminum. Other suitable material may be used such as glass, plastic or carbon fiber resin. The panels **8** and **10** may be sheet metal. The panels **8** and **10** may be provided with compartments or other structure to hold accessories such as screwdrivers or other tools.

A second embodiment of the hand truck is shown in FIGS. 11 and 12. In this embodiment an alternative handle arrangement is provided that comprises two independent handles **122** each having a post **124** mounted in a channel in one of the outside columns **102** or **106**. A handle portion **125** is attached to the distal end of each post **124** and extends perpendicular therefrom. Each handle **122** is vertically adjustable between a lower position as shown in FIG. 11 and an upper position as shown in FIG. 12. Each handle **122** is rotatable about the axis of its post **124** as indicated in FIG. 12. Suitable locking mechanisms may be provided to lock each handle in its various positions.

With the alternative handle arrangement, the handles **122** can be set to multiple positions independently. The locking mechanism may include a detent button (not shown) that may be pushed and each handle may be adjusted vertically (up to 24 inches as an example) to a comfortable height for the operator. The adjustable vertical feature can be used when going up or down stairs or for transporting a tall load. Additionally, the handle portions **125** can be rotated and locked pointing away from each other for more torque and stability, or locked at 45 degrees back toward the operator for comfort when transporting loads long distances. The handle portions **125** may be locked pointing toward each other in the case only a single hand is available to grip the handle portions in the center of the hand truck to move the load by a single hand.

This embodiment may have three spaced columns **102**, **104** and **106** similar to the previous embodiment. Top and bottom

5

cross brackets **112** interconnect the three spaced columns **102**, **104** and **106**. Spaced wheels **116** and **118** are connected to the bottom cross bracket to the rear of the hand truck. A suitable motor may be provided to motorize the wheels **116** to provide a means for propelling the hand truck. Panels such as panels **8** and **10** shown in FIGS. **1, 2** and **3** may be provided in this embodiment, and the tension rods **15** may also be included.

As in the previous embodiment, the hand truck includes two toe plates, an upper toe plate **118** and a lower toe plate **120**. The lower toe plate **120** is stationary during use to provide stability while lifting. The upper toe plate **118** provides a lifting platform and is moveable upwardly and downwardly in a vertical direction along the columns **2** and **6**. Both the upper toe plate **118** and the lower toe plate **120** are pivotal upwardly into a collapsed position as shown in FIG. **11** wherein they extend vertically parallel to the elongated columns **2**, **4** and **6**.

As indicated in FIG. **13**, the bottom toe plate **120** is attached to the bottom cross bracket **114** by pins and a lock mechanism so that it can be locked in an operational position extending from the columns as shown in FIG. **12** or pivoted and locked in a storage position extending generally parallel to the columns as shown in FIG. **11**. The upper toe plate **120** is attached to a lifting toe plate backplate **155** via a hinge with a pin and latch mechanism on the side to permit rotation and locking of the upper toe plate **120** in a storage position as shown in FIG. **11** or in an operational position extending from the columns as shown in FIG. **12**.

The lifting toe plate backplate **155** is rigidly attached to a yoke **156** to which the rollers **132** are secured. The rollers **132** are mounted in the outer columns **102** and **106** as shown in FIG. **10**. The yoke **156** is attached to a lifting bracket **146** which in turn is attached to the lead screw nut **145**.

As shown in FIGS. **14** and **14A**, the lifting bracket **146** includes a plate portion **157** that is connected to the yoke **156** and two vertically spaced bosses **158** secured to the plate by a rearward extending flange **159**. Each boss **158** has a through bore **160** which slidably receives the lead screw **144**. The lead screw nut **145**, which is threaded on the lead screw **114**, is captured between the two bosses **158** so that rotation of the lead screw **144** causes the lead screw nut **145**, along with the lifting bracket **146**, yoke **156** and upper toe plate **118** to move vertically up and down along the columns **102** and **106**.

As shown in FIG. **15** the bottom toe plate **120** is generally U-shaped with a forward portion **174** and two legs **176** extending rearward from the sides of the forward portion **174**. The forward edge **178** of the bottom toe plate **120** is provided with an L-shaped cutout **180**.

As shown in FIG. **16**, the upper toe plate **118** includes a planar portion **182** having a front edge with an L-shaped cutout **184** to match the L-shaped cutout **180** of the bottom toe plate **120**. The forward end of the top surface of the planar portion is tapered downwardly and forwardly as indicated at **186**. Forwardly and downward tapering sides **188** extend upwardly at both sides of the planar portion **182**.

As shown particularly in FIGS. **17**, **17A**, a side skirt **189** extends downward from the bottom of the planar portion at either side of the upper toe plate **118**. The side skirts **189** are spaced apart a distance such that when the upper toe plate **118** is in its lower position, the bottom toe plate **120** is nested between the side skirts **189** with the side skirts **189** overlapping the side edges of the bottom toe plate **120**. The forward end **186** of the upper toe plate **118** may extend forwardly beyond the forward edge of the bottom toe plate **120**.

6

The upper surface of the planar portion of the upper toe plate may be provided with downwardly and forwardly tapering wedges **190** as shown in FIGS. **16** and **17**, **17A** to assist in the scooping of a load.

The drive arrangement may include a motor **145** as shown in FIG. **18** mounted on the lower cross bracket **114** by a motor mount **147**. The motor **145** is attached to a suitable gearbox **149** that is attached to a clutch **150**. The clutch **150** has a shaft protruding through the lower cross bracket **114** that is attached to a gear that is attached to another gear on the lead screw **144**.

A removable battery holder **151** is mounted on the upper cross bracket **112** and has mounted therein a rechargeable battery **153** adapted to be recharged by a plug-in battery charging station **155**. The battery **153** is wired to a potentiometer trigger **157**, an up/down toggle switch **159** and the motor **145**, with the wiring, where convenient, passing through the center column **104**. The battery **145** may be a rechargeable lithium 18v battery.

In operation, the operator would take the hand truck folded for storage and unlatch the bottom toe plate **120** and upper toe plate **118** from their folded position and rotate them outward until they are locked in their operable position, general perpendicular to the columns **102** and **106**. The removable battery **153** would be placed in its holder **151** and, while the up/down toggle switch **159** is set to down, would depress the trigger **157** to start the motor **145** and move the upper toe plate **118** down to its lowest position nesting over the bottom toe plate **120**. The operator would then move the hand truck into position using the wheels **116** and ram the tapered front edge of the upper toe plate **118** underneath the load. To lift the load, the operator would lock the wheels **116** in the "parked" mode and change the up/down toggle switch **159** to up. The operator would press the trigger **157** to raise the load until the desired height is reached or until the upper limit is reached and the clutch **150** makes a clicking sound and there is no more vertical movement.

As shown in FIG. **19**, the wheels **116** may have tires provided with cogs **165** around their periphery. The cogs will grip the stair tread to assist the hand truck in climbing stairs.

An inertia brake (not shown) may be provided for catastrophic failure of the nut and lead screw connection. A three axis accelerometer may also be provided with appropriate circuitry to prevent lifting if tipping.

With the above described arrangement, a hand truck is provided that is easy to operate, relatively light in weight, cost efficient and ergonomic.

The invention claimed is:

1. A hand truck for carrying and lifting a load comprising:
 - spaced vertical columns each having a channel and a middle column;
 - rollers captured in each of said channels capable of vertical movement along a said respective channel;
 - a first toe plate affixed to said columns and adapted to extend horizontally during use;
 - a second toe plate adapted to move vertically along said columns between upper and lower positions; said first and second toe plates being in nesting relationship with each other when said second toe plate is in its lower position;
 - a lifting toe plate backplate, said second toe plate being secured to said lifting toe plate backplate;
 - a yoke to which said lifting toe plate back plate is secured, said rollers extending from said yoke;
 - a lead screw received in said middle column,
 - a lifting bracket attached to said yoke, said lifting bracket being attached by a nut to said lead screw so that upon

7

rotation of said lead screw, said second toe plate is moved vertically along said columns.

2. The hand truck of claim 1 wherein the first toe plate is generally U-shaped with a forward portion, and two leg portions extending rearward from said forward portion, said forward portion and said leg portions surrounding said second toe plate when said second toe plate is in its lower position.

3. The hand truck of claim 2 wherein said first and second toe plates have upper surfaces that are coplanar when said second toe plate is in its lower position.

4. The hand truck of claim 1 wherein said first and second toe plates are rotatable into a vertical position substantially parallel to said columns for storage.

5. The hand truck of claim 1 wherein said first toe plate has a forward edge provided with an L-shaped cutout.

6. The hand truck of claim 1 wherein said second toe plate has spaced side skirts extending downward from its side edges that cover the side edges of the first toe plate when said second toe plate is in its lower position whereby said first toe plate is nested between said side skirts of said second toe plate.

7. The hand truck of claim 6 wherein the second toe plate has a planar upper surface with a tapered portion at its forward end, said upper surface having at least one wedge thereon that tapers forwardly and downwardly.

8. The hand truck of claim 1 further including a handle having at least one post telescopically received in one of said spaced columns whereby said handle can be raised and lowered.

9. The hand truck of claim 1 wherein said hand truck includes two independent handles each having a post telescopically received in one of said spaced columns, each said

8

posts having a handle portion attached thereto, said handles being rotatable about the axis of the post.

10. The hand truck of claim 1 wherein said channels for said rollers have opposed convex walls and said rollers have an outer concave surface mating with said convex walls of said channel.

11. The hand truck of claim 10 wherein one edge of each roller has a diameter larger than the diameter of the other edge and the convex walls have a contour to mate with the contour of the outer surface of said roller.

12. The hand truck of claim 1 wherein said center column is positioned centrally between the two spaced vertical columns and panels, one on each side of said center column are positioned between the center column and a respective spaced vertical panel.

13. The hand truck of claim 1 further including top and bottom cross brackets at the top and bottom of said columns, and tension rods extending through a channel in said columns and holding the top and bottom cross brackets against said columns.

14. The hand truck of claim 1 further including top and bottom cross brackets secured to the top and bottom of said columns respectively, and further including wheels attached to said bottom cross bracket for moving said hand truck, said wheels having tires with cogs.

15. The hand truck of claim 1 further including top and bottom cross brackets secured to the top and bottom of said columns respectively, and further including a motor secured to said bottom bracket.
